LT1028/LT1128

## FEATURES

- Voltage Noise
1.1nV/ $/ \mathrm{Hz}$ Max at 1 kHz
$0.85 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Typ at 1 kHz
$1.0 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Typ at 10 Hz
35 nV p-p Typ, 0.1 Hz to 10 Hz
- Voltage and Current Noise 100\% Tested
- Gain-Bandwidth Product

LT1028: 50MHz Min
LT1128: 13MHz Min

- Slew Rate

LT1028: 11V/us Min
LT1128: 5V/us Min

- Offset Voltage: $40 \mu \mathrm{~V}$ Max
- Drift with Temperature: $0.8 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ Max
- Voltage Gain: 7 Million Min
- Available in 8-Lead SO Package

## APPLICATIONS

- Low Noise Frequency Synthesizers
- High Quality Audio
- Infrared Detectors
- Accelerometer and Gyro Amplifiers
- $350 \Omega$ Bridge Signal Conditioning
- Magnetic Search Coil Amplifiers
- Hydrophone Amplifiers

## Ultralow Noise Precision High Speed Op Amps

## DESCRIPTIOn

The LT® ${ }^{\text {10 }}$ 1028(gain of -1 stable)/LT1128(gain of +1 stable) achieve a new standard of excellence in noise performance with $0.85 \mathrm{nV} / \sqrt{\mathrm{Hz}} 1 \mathrm{kHz}$ noise, $1.0 \mathrm{nV} / \sqrt{\mathrm{Hz}} 10 \mathrm{~Hz}$ noise. This ultralow noise is combined with excellent high speed specifications (gain-bandwidth product is 75 MHz for LT1028, 20MHz for LT1128), distortion-free output, and true precision parameters $\left(0.1 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}\right.$ drift, $10 \mu \mathrm{~V}$ offset voltage, 30 million voltage gain). Although the LT1028/ LT1128 input stage operates at nearly 1 mA of collector current to achieve low voltage noise, input bias current is only $25 n A$.

The LT1028/LT1128's voltage noise is less than the noise of a $50 \Omega$ resistor. Therefore, even in very low source impedance transducer or audio amplifier applications, the LT1028/LT1128's contribution to total system noise will be negligible.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: Input Offset Voltage measurements are performed by automatic test equipment approximately 0.5 sec . after application of power. In addition, at $T_{A}=25^{\circ} \mathrm{C}$, offset voltage is measured with the chip heated to approximately $55^{\circ} \mathrm{C}$ to account for the chip temperature rise when the device is fully warmed up.
Note 3: Long Term Input Offset Voltage Stability refers to the average trend line of Offset Voltage vs Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in $\mathrm{V}_{0 S}$ during the first 30 days are typically $2.5 \mu \mathrm{~V}$.
Note 4: This parameter is tested on a sample basis only.
Note 5: 10 Hz noise voltage density is sample tested on every lot with the exception of the S8 and S16 packages. Devices $100 \%$ tested at 10 Hz are available on request.

Note 6: Current noise is defined and measured with balanced source resistors. The resultant voltage noise (after subtracting the resistor noise on an RMS basis) is divided by the sum of the two source resistors to obtain current noise. Maximum 10 Hz current noise can be inferred from $100 \%$ testing at 1 kHz .
Note 7: Gain-bandwidth product is not tested. It is guaranteed by design and by inference from the slew rate measurement.
Note 8: This parameter is not $100 \%$ tested.
Note 9: The inputs are protected by back-to-back diodes. Current-limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds $\pm 1.8 \mathrm{~V}$, the input current should be limited to 25 mA .
Note 10: This parameter guaranteed by design, fully warmed up at $T_{A}$ $=70^{\circ} \mathrm{C}$. It includes chip temperature increase due to supply and load currents.
Note 11: The LT1028/LT1128 are designed, characterized and expected to meet these extended temperature limits, but are not tested at $-40^{\circ} \mathrm{C}$ and $85^{\circ} \mathrm{C}$. Guaranteed I-grade parts are available. Consult factory.

Voltage Noise vs Current Noise

The LT1028/LT1128's less than $1 \mathrm{nV} / \sqrt{H z}$ voltage noise is three times better than the lowest voltage noise heretofore available (on the LT1007/1037). A necessary condition for such low voltage noise is operating the input transistors at nearly 1 mA of collector currents, because voltage noise is inversely proportional to the square root of the collector current. Current noise, however, is directly proportional to the square root of the collector current. Consequently, the LT1028/LT1128's current noise is significantly higher than on most monolithic op amps.

Therefore, to realize truly low noise performance it is important to understand the interaction between voltage noise $\left(e_{n}\right)$, current noise $\left(I_{n}\right)$ and resistor noise ( $r_{n}$ ).

## Total Noise vs Source Resistance

The total input referred noise of an op amp is given by:

$$
e_{t}=\left[e_{n}^{2}+r_{n}^{2}+\left(I_{n} R_{e q}\right)^{2}\right]^{1 / 2}
$$

where $R_{\text {eq }}$ is the total equivalent source resistance at the two inputs, and

$$
r_{n}=\sqrt{4 \mathrm{kTR}_{\mathrm{eq}}}=0.13 \sqrt{\operatorname{Req}} \text { in } \mathrm{nV} / \sqrt{\mathrm{Hz}} \text { at } 25^{\circ} \mathrm{C}
$$

As a numerical example, consider the total noise at 1 kHz of the gain 1000 amplifier shown in Figure 1.

Figure 1

$$
\begin{aligned}
& \mathrm{R}_{\text {eq }}=100 \Omega+100 \Omega \| 100 \mathrm{k} \approx 200 \Omega \\
& r_{\mathrm{n}}=0.13 \sqrt{200}=1.84 \mathrm{nV} \sqrt{\mathrm{~Hz}} \\
& \mathrm{e}_{\mathrm{n}}=0.85 \mathrm{nV} \sqrt{\mathrm{~Hz}} \\
& \mathrm{I}_{\mathrm{n}}=1.0 \mathrm{pA} / \sqrt{\mathrm{Hz}} \\
& \mathrm{e}_{\mathrm{t}}=\left[0.85^{2}+1.84^{2}+(1.0 \times 0.2)^{2}\right]^{1 / 2}=2.04 \mathrm{nV} / \sqrt{\mathrm{Hz}} \\
& \text { Output noise }=1000 \mathrm{e}_{\mathrm{t}}=2.04 \mu \mathrm{~V} / \sqrt{\mathrm{Hz}}
\end{aligned}
$$

At very low source resistance ( $\mathrm{R}_{\mathrm{eq}}<40 \Omega$ ) voltage noise dominates. As $\mathrm{R}_{\text {eq }}$ is increased resistor noise becomes
the largest term, as in the example above, and the LT1028/ LT1128's voltage noise becomes negligible. As $\mathrm{R}_{\text {eq }}$ is further increased, current noise becomes important. At 1 kHz , when $\mathrm{R}_{\text {eq }}$ is in excess of 20 k , the current noise component is larger than the resistor noise. The total noise versus matched source resistance plot illustrates the above calculations.

The plot also shows that current noise is more dominant at low frequencies, such as 10 Hz . This is because resistor noise is flat with frequency, while the $1 / f$ corner of current noise is typically at 250 Hz . At 10 Hz when $R_{\text {eq }}>1 \mathrm{k}$, the current noise term will exceed the resistor noise.

When the source resistance is unmatched, the total noise versus unmatched source resistance plot should be consulted. Note that total noise is lower at source resistances below 1 k because the resistor noise contribution is less. When $R_{S}>1 k$ total noise is not improved, however. This is because bias current cancellation is used to reduce input bias current. The cancellation circuitry injects two correlated current noise components into the two inputs. With matched source resistors the injected current noise creates a common-mode voltage noise and gets rejected by the amplifier. With source resistance in one input only, the cancellation noise is added to the amplifier's inherent noise.

In summary, the LT1028/LT1128 are the optimum amplifiers for noise performance, provided that the source resistance is kept low. The following table depicts which op amp manufactured by Linear Technology should be used to minimize noise, as the source resistance is increased beyond the LT1028/LT1128's level of usefulness.

Table 1. Best Op Amp for Lowest Total Noise vs Source Resistance

| SOURCE RESIS- <br> TANCE $(\boldsymbol{\Omega})($ Note 1) | BEST OP AMP |  |
| :---: | :---: | :---: |
|  | AT LOW FREQ (10Hz) | WIDEBAND (1kHz) |
| 0 to 400 | LT1028/LT1128 | LT1028/LT1128 |
| 400 to 4k | LT1007/1037 | LT1028/LT1128 |
| $4 k$ to 40k | LT1001 | LT1007/LT1037 |
| 40 k to 500k | LT1012 | LT1001 |
| 500 k to 5M | LT1012 or LT1055 | LT1012 |
| $>5 \mathrm{M}$ | LT1055 | LT1055 |

Note 1: Source resistance is defined as matched or unmatched, e.g., $R_{S}=1 k$ means: $1 k$ at each input, or $1 k$ at one input and zero at the other.

## APPLICATIONS INFORMATION - חOISE

Noise Testing - Voltage Noise
The LT1028/LT1128's RMS voltage noise density can be accurately measured using the Quan Tech Noise Analyzer, Model 5173 or an equivalent noise tester. Care should be taken, however, to subtract the noise of the source resistor used. Prefabricated test cards for the Model 5173 set the device under test in a closed-loop gain of 31 with a $60 \Omega$ source resistor and a 1.8 k feedback resistor. The noise of this resistor combination is $0.13 \sqrt{58}=1.0 \mathrm{nV} / \sqrt{\mathrm{Hz}}$. An LT1028/LT1128 with $0.85 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ noise will read $\left(0.85^{2}+\right.$ $\left.1.0^{2}\right)^{1 / 2}=1.31 \mathrm{nV} / \sqrt{\mathrm{Hz}}$. For better resolution, the resistors should be replaced with a $10 \Omega$ source and $300 \Omega$ feedback resistor. Even a $10 \Omega$ resistor will show an apparent noise which is $8 \%$ to $10 \%$ too high.
The 0.1 Hz to 10 Hz peak-to-peak noise of the LT1028/ LT1128 is measured in the test circuit shown. The frequency response of this noise tester indicates that the 0.1 Hz corner is defined by only one zero. The test time to measure 0.1 Hz to 10 Hz noise should not exceed 10 seconds, as this time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1 Hz .

Measuring the typical 35 nV peak-to-peak noise performance of the LT1028/LT1128 requires special test precautions:
(a) The device should be warmed up for at least five minutes. As the op amp warms up, its offset voltage changes typically $10 \mu \mathrm{~V}$ due to its chip temperature increasing $30^{\circ} \mathrm{C}$ to $40^{\circ} \mathrm{C}$ from the moment the power supplies are turned on. In the 10 second measurement interval these temperature-induced effects can easily exceed tens of nanovolts.
(b) For similar reasons, the device must be well shielded from air current to eliminate the possibility of thermoelectric effects in excess of a few nanovolts, which would invalidate the measurements.
(c) Sudden motion in the vicinity of the device can also feedthrough to increase the observed noise.

A noise-voltage density test is recommended when measuring noise on a large number of units. A 10 Hz noise-voltage density measurement will correlate well with a 0.1 Hz to 10 Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the $1 / f$ corner frequency.

Figure 2. 0.1 Hz to 10 Hz Noise Test Circuit

Figure 3. 0.1Hz to 10Hz Peak-to-Peak Noise Tester Frequency Response

## APPLICATIONS INFORMATION - חOIS

Noise Testing - Current Noise
Current noise density $\left(I_{n}\right)$ is defined by the following formula, and can be measured in the circuit shown in Figure 4.

$$
I_{n}=\frac{\left[\mathrm{e}_{n o}{ }^{2}-(31 \cdot 18.4 \mathrm{nV} / \sqrt{\mathrm{Hz}})^{2}\right]^{1 / 2}}{20 \mathrm{k} \cdot 31}
$$

Figure 4
If the Quan Tech Model 5173 is used, the noise reading is input-referred, therefore the result should not be divided by 31 ; the resistor noise should not be multiplied by 31 .

## 100\% Noise Testing

The 1 kHz voltage and current noise is $100 \%$ tested on the LT1028/LT1128 as part of automated testing; the approximate frequency response of the filters is shown. The limits on the automated testing are established by extensive correlation tests on units measured with the Quan Tech Model 5173.

10 Hz voltage noise density is sample tested on every lot. Devices $100 \%$ tested at 10 Hz are available on request for an additional charge.

10 Hz current noise is not tested on every lot but it can be inferred from $100 \%$ testing at 1 kHz . A look at the current noise spectrum plot will substantiate this statement. The only way 10 Hz current noise can exceed the guaranteed limits is if its $1 / f$ corner is higher than 800 Hz and/or its white noise is high. If that is the case then the 1 kHz test will fail.

Figure 5. Automated Tester Noise Filter

## LT1028/LT1 128

## APPLICATIONS INFORMATION

General
The LT1028/LT1128 series devices may be inserted directly into OP-07, OP-27, OP-37, LT1007 and LT1037 sockets with or without removal of external nulling components. In addition, the LT1028/LT1128 may be fitted to 5534 sockets with the removal of external compensation components.

## Offset Voltage Adjustment

The input offset voltage of the LT1028/LT1128 and its drift with temperature, are permanently trimmed at wafer testing to a low level. However, if further adjustment of $\mathrm{V}_{\mathrm{OS}}$ is necessary, the use of a 1 k nulling potentiometer will not degrade drift with temperature. Trimming to a value other than zero creates a drift of $\left(\mathrm{V}_{0 S} / 300\right) \mu \mathrm{V} /{ }^{\circ} \mathrm{C}$, e.g., if $\mathrm{V}_{0 S}$ is adjusted to $300 \mu \mathrm{~V}$, the change in drift will be $1 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$.
The adjustment range with a 1 k pot is approximately $\pm 1.1 \mathrm{mV}$.

Figure 6

## Offset Voltage and Drift

Thermocouple effects, caused by temperature gradients across dissimilar metals at the contacts to the input terminals, can exceed the inherent drift of the amplifier unless proper care is exercised. Air currents should be minimized, package leads should be short, the two input leads should be close together and maintained at the same temperature.

The circuit shown in Figure 7 to measure offset voltage is also used as the burn-in configuration for the LT1028/ LT1128.

Figure 7. Test Circuit for Offset Voltage and Offset Voltage Drift with Temperature

## Unity-Gain Buffer Applications (LT1128 Only)

When $R_{F} \leq 100 \Omega$ and the input is driven with a fast, largesignal pulse (>1V), the output waveform will look as shown in the pulsed operation diagram (Figure 8).

Figure 8

During the fast feedthrough-like portion of the output, the input protection diodes effectively short the output to the input and a current, limited only by the output short-circuit protection, will be drawn by the signal generator. With $R_{F} \geq 500 \Omega$, the output is capable of handling the current requirements ( $\mathrm{L}_{\mathrm{L}} \leq 20 \mathrm{~mA}$ at 10 V ) and the amplifier stays in its active mode and a smooth transition will occur.

As with all operational amplifiers when $R_{F}>2 k$, a pole will be created with RF and the amplifier's input capacitance, creating additional phase shift and reducing the phase margin. A small capacitor (20pF to 50pF) in parallel with $R_{F}$ will eliminate this problem.

## APPLICATIONS INFORMATION

## Frequency Response

The LT1028's Gain, Phase vs Frequency plot indicates that the device is stable in closed-loop gains greater than +2 or -1 because phase margin is about $50^{\circ}$ at an open-loop gain of 6dB. In the voltage follower configuration phase margin seems inadequate. This is indeed true when the output is shorted to the inverting input and the noninverting input is driven from a $50 \Omega$ source impedance. However, when feedback is through a parallel R-C network (provided $\mathrm{C}_{\mathrm{F}}$ $<68 \mathrm{pF}$ ), the LT1028 will be stable because of interaction between the input resistance and capacitance and the feedback network. Larger source resistance at the noninverting input has a similar effect. The following voltage follower configurations are stable:

Figure 9
Another configuration which requires unity-gain stability is shown below. When $C_{F}$ is large enough to effectively short the output to the input at 15 MHz , oscillations can occur. The insertion of $\mathrm{R}_{\mathrm{S} 2} \geq 500 \Omega$ will prevent the LT1028 from oscillating. When $R_{S 1} \geq 500 \Omega$, the additional noise contribution due to the presence of $R_{S 2}$ will be minimal. When $R_{S 1} \leq 100 \Omega, R_{S 2}$ is not necessary, because $R_{S 1}$ represents a heavy load on the output through the $\mathrm{C}_{\mathrm{F}}$ short. When $100 \Omega<R_{S 1}<500 \Omega$, $R_{S 2}$ should match $R_{S 1}$. For example, $R_{S 1}=R_{S 2}=300 \Omega$ will be stable. The noise increase due to $\mathrm{R}_{\mathrm{S} 2}$ is $40 \%$.

Figure 10
If $\mathrm{C}_{\mathrm{F}}$ is only used to cut noise bandwidth, a similar effect can be achieved using the over-compensation terminal.

The Gain, Phase plot also shows that phase margin is about $45^{\circ}$ at gain of $10(20 \mathrm{~dB})$. The following configuration has a high ( $\approx 70 \%$ ) overshoot without the 10pF capacitor because of additional phase shift caused by the feedback resistor-input capacitance pole. The presence of the 10pF capacitor cancels this pole and reduces overshoot to $5 \%$.

Figure 11

## Over-Compensation

The LT1028/LT1128 are equipped with a frequency overcompensation terminal (Pin 5). A capacitor connected between Pin 5 and the output will reduce noise bandwidth. Details are shown onthe Slew Rate, Gain-Bandwidth Product vs Over-Compensation Capacitor plot. An additional benefit is increased capacitive load handling capability.

## LT1028/LT1 128

TYPICAL APPLICATIONS

Strain Gauge Signal Conditioner with Bridge Excitation

Low Noise Voltage Regulator

## TYPICAL APPLICATIONS

Paralleling Amplifiers to Reduce Voltage Noise

1. ASSUME VOLTAGE NOISE OF LT1028 AND $7.5 \Omega$ SOURCE RESISTOR $=0.9 \mathrm{nV} / \sqrt{\mathrm{Hz}}$.
2. GAIN WITH $n$ LT1028s IN PARALLEL $=n \bullet 200$
3. OUTPUT NOISE $=\sqrt{n} \cdot 200 \cdot 0.9 \mathrm{nV} / \sqrt{\mathrm{Hz}}$.
4. INPUT REFERRED NOISE $=\frac{\text { OUTPUT NOISE }}{n \cdot 200}=\frac{0.9}{\sqrt{n}} \mathrm{nV} / \sqrt{\mathrm{Hz}}$.
5. NOISE CURRENT AT INPUT INCREASES $\sqrt{n}$ TIMES.
6. IF $\mathrm{n}=5, \mathrm{GAIN}=1000$, BANDWIDTH $=1 \mathrm{MHz}$, RMS NOISE, DC TO $1 \mathrm{MHz}=\frac{2 \mu \mathrm{~V}}{\sqrt{5}}=0.9 \mu \mathrm{~V}$.
