## DATA SHEET

# TEA1062; TEA1062A Low voltage transmission circuits with dialler interface 

Product specification
File under Integrated Circuits, IC03

Low voltage transmission circuits with dialler interface

## FEATURES

- Low DC line voltage; operates down to 1.6 V (excluding polarity guard)
- Voltage regulator with adjustable static resistance
- Provides a supply for external circuits
- Symmetrical high-impedance inputs ( $64 \mathrm{k} \Omega$ ) for dynamic, magnetic or piezoelectric microphones
- Asymmetrical high-impedance input ( $32 \mathrm{k} \Omega$ ) for electret microphones
- DTMF signal input with confidence tone
- Mute input for pulse or DTMF dialling
- TEA1062: active HIGH (MUTE)
- TEA1062A: active LOW (MUTE)
- Receiving amplifier for dynamic, magnetic or piezoelectric earpieces
- Large gain setting ranges on microphone and earpiece amplifiers
- Line loss compensation (line current dependent) for microphone and earpiece amplifiers
- Gain control curve adaptable to exchange supply
- DC line voltage adjustment facility.

## GENERAL DESCRIPTION

The TEA1062 and TEA1062A are integrated circuits that perform all speech and line interface functions required in fully electronic telephone sets. They perform electronic switching between dialling and speech. The ICs operate at line voltage down to 1.6 V DC (with reduced performance) to facilitate the use of more telephone sets connected in parallel.

All statements and values refer to all versions unless otherwise specified.

Low voltage transmission circuits with dialler interface

## FUNCTIONAL DESCRIPTION

## Supplies V $_{\text {Cc }}$, LN, SLPE, REG and STAB

Power for the IC and its peripheral circuits is usually obtained from the telephone line. The supply voltage is derived from the line via a dropping resistor and regulated by the IC. The supply voltage $\mathrm{V}_{\mathrm{CC}}$ may also be used to supply external circuits e.g. dialling and control circuits.

Decoupling of the supply voltage is performed by a capacitor between $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{EE}}$. The internal voltage regulator is decoupled by a capacitor between REG and $V_{E E}$.

The DC current flowing into the set is determined by the exchange supply voltage $V_{\text {exch }}$, the feeding bridge resistance $\mathrm{R}_{\text {exch }}$ and the DC resistance of the telephone line $\mathrm{R}_{\text {line }}$.
The circuit has an internal current stabilizer operating at a level determined by a $3.6 \mathrm{k} \Omega$ resistor connected between STAB and $\mathrm{V}_{\mathrm{EE}}$ (see Fig.9). When the line current (line) is more than 0.5 mA greater than the sum of the IC supply current ( $I_{\mathrm{CC}}$ ) and the current drawn by the peripheral circuitry connected to $\mathrm{V}_{\mathrm{CC}}\left(\mathrm{I}_{\mathrm{p}}\right)$ the excess current is shunted to $\mathrm{V}_{\mathrm{EE}}$ via LN.

The regulated voltage on the line terminal ( $\mathrm{V}_{\mathrm{LN}}$ ) can be calculated as:

$$
\begin{aligned}
& V_{\mathrm{LN}}=V_{\text {ref }}+I_{\text {SLPE }} \times R 9 \\
& V_{\mathrm{LN}}=V_{\text {ref }}+\left\{\left(I_{\text {line }}-I_{\text {CC }}-0.5 \times 10^{-3} \mathrm{~A}\right)-I_{p}\right\} \times R 9
\end{aligned}
$$

$\mathrm{V}_{\text {ref }}$ is an internally generated temperature compensated reference voltage of 3.7 V and R 9 is an external resistor connected between SLPE and $\mathrm{V}_{\mathrm{EE}}$.

In normal use the value of R9 would be $20 \Omega$.
Changing the value of R 9 will also affect microphone gain, DTMF gain, gain control characteristics, sidetone level, maximum output swing on LN and the DC characteristics (especially at the lower voltages).

Under normal conditions, when $I_{\text {SLPE }} \gg I_{C C}+0.5 \mathrm{~mA}+\mathrm{I}_{\mathrm{p}}$, the static behaviour of the circuit is that of a 3.7 V regulator diode with an internal resistance equal to that of R9. In the audio frequency range the dynamic impedance is largely determined by R1. Fig. 3 shows the equivalent impedance of the circuit.

Fig. 3 Equivalent impedance circuit.

At line currents below 9 mA the internal reference voltage is automatically adjusted to a lower value (typically 1.6 V at 1 mA ). This means that more sets can be operated in parallel with DC line voltages (excluding the polarity guard) down to an absolute minimum voltage of 1.6 V . At line currents below 9 mA the circuit has limited sending and receiving levels. The internal reference voltage can be adjusted by means of an external resistor ( $\mathrm{R}_{\mathrm{VA}}$ ). This resistor when connected between LN and REG will decrease the internal reference voltage and when connected between REG and SLPE will increase the internal reference voltage.

Current $\left(I_{p}\right)$ available from $V_{C C}$ for peripheral circuits depends on the external components used. Fig. 10 shows this current for $\mathrm{V}_{\mathrm{CC}}>2.2 \mathrm{~V}$. If MUTE is LOW (TEA1062) or MUTE is HIGH (TEA1062A) when the receiving amplifier is driven, the available current is further reduced. Current availability can be increased by connecting the supply IC (TEA1081) in parallel with R1 as shown in Fig. 19 and Fig.20, or by increasing the DC line voltage by means of an external resistor ( $\mathrm{R}_{\mathrm{VA}}$ ) connected between REG and SLPE (Fig.18).

# Low voltage transmission circuits with 

 dialler interface
## Microphone inputs MIC+ and MIC- and gain pins GAS1 and GAS2

The circuit has symmetrical microphone inputs. Its input impedance is $64 \mathrm{k} \Omega(2 \times 32 \mathrm{k} \Omega)$ and its voltage gain is typically 52 dB (when R7 $=68 \mathrm{k} \Omega$, see Figures 14 and 15). Dynamic, magnetic, piezoelectric or electret (with built-in FET source followers) can be used. Microphone arrangements are illustrated in Fig. 11.

The gain of the microphone amplifier can be adjusted between 44 dB and 52 dB to suit the sensitivity of the transducer in use. The gain is proportional to the value of R7 which is connected between GAS1 and GAS2.

Stability is ensured by two external capacitors, C6 connected between GAS1 and SLPE and C8 connected between GAS1 and $\mathrm{V}_{\mathrm{EE}}$. The value of C 6 is 100 pF but this may be increased to obtain a first-order low-pass filter. The value of C 8 is 10 times the value of C 6 . The cut-off frequency corresponds to the time constant R7 $\times \mathrm{C} 6$.

## Input MUTE (TEA1062)

When MUTE is HIGH the DTMF input is enabled and the microphone and receiving amplifier inputs are inhibited. The reverse is true when MUTE is LOW or open-circuit. MUTE switching causes only negligible clicking on the line and earpiece output. If the number of parallel sets in use causes a drop in line current to below 6 mA the speech amplifiers remain active independent to the DC level applied to the MUTE input.

## Input MUTE (TEA1062A)

When $\overline{\text { MUTE }}$ is LOW or open-circuit, the DTMF input is enabled and the microphone and receiving amplifier inputs are inhibited. The reverse is true when MUTE is HIGH. $\overline{\text { MUTE }}$ switching causes only negligible clicking on the line and earpiece output. If the number of parallel sets in use causes a drop in line current to below 6 mA the DTMF amplifier becomes active independent to the DC level applied to the MUTE input.

## Dual-tone multi-frequency input DTMF

When the DTMF input is enabled dialling tones may be sent on to the line. The voltage gain from DTMF to LN is typically 25.5 dB (when R7 = 68 k $\Omega$ ) and varies with R7 in the same way as the microphone gain. The signalling tones can be heard in the earpiece at a low level (confidence tone).

## Receiving amplifier IR, QR and GAR

The receiving amplifier has one input (IR) and a non-inverting output (QR). Earpiece arrangements are illustrated in Fig.12. The IR to QR gain is typically 31 dB (when R4 $=100 \mathrm{k} \Omega$ ). It can be adjusted between 20 and 31 dB to match the sensitivity of the transducer in use. The gain is set with the value of $R 4$ which is connected between GAR and QR. The overall receive gain, between LN and QR, is calculated by subtracting the anti-sidetone network attenuation ( 32 dB ) from the amplifier gain. Two external capacitors, C 4 and C 7 , ensure stability. C4 is normally 100 pF and C7 is 10 times the value of C 4 . The value of C 4 may be increased to obtain a first-order low-pass filter. The cut-off frequency will depend on the time constant R4×C4.

The output voltage of the receiving amplifier is specified for continuous-wave drive. The maximum output voltage will be higher under speech conditions where the peak to RMS ratio is higher.

## Automatic Gain Control input AGC

Automatic line loss compensation is achieved by connecting a resistor (R6) between AGC and $\mathrm{V}_{\mathrm{EE}}$.

The automatic gain control varies the gain of the microphone amplifier and the receiving amplifier in accordance with the DC line current. The control range is 5.8 dB which corresponds to a line length of 5 km for a 0.5 mm diameter twisted-pair copper cable with a DC resistance of $176 \Omega / \mathrm{km}$ and average attenuation of $1.2 \mathrm{~dB} / \mathrm{km}$ ). Resistor R6 should be chosen in accordance with the exchange supply voltage and its feeding bridge resistance (see Fig. 13 and Table 1). The ratio of start and stop currents of the AGC curve is independent of the value of R6. If no automatic line-loss compensation is required the AGC pin may be left open-circuit. The amplifiers, in this condition, will give their maximum specified gain.

## Low voltage transmission circuits with dialler interface

## Sidetone suppression

The anti-sidetone network, R1//Z line , R2, R3, R8, R9 and $\mathrm{Z}_{\text {bal }}$, (see Fig.4) suppresses the transmitted signal in the earpiece. Maximum compensation is obtained when the following conditions are fulfilled:

$$
\begin{gather*}
R 9 \times R 2=R 1 \times\left(R 3+\frac{R 8 \times Z_{\text {bal }}}{R 8+Z_{\text {bal }}}\right)  \tag{1}\\
\frac{Z_{\text {bal }}}{Z_{\text {bal }}+R 8}=\frac{Z_{\text {line }}}{Z_{\text {line }}+R 1} \tag{2}
\end{gather*}
$$

If fixed values are chosen for R1, R2, R3 and R9, then condition (1) will always be fulfilled when $\mid R 8 / / Z_{\text {bal }} \ll R 3$.
To obtain optimum sidetone suppression, condition (2) has to be fulfilled which results in:

$$
Z_{\text {bal }}=\frac{R 8}{R 1} \times Z_{\text {line }}=k \times Z_{\text {line }}
$$

Where $k$ is a scale factor; $k=\frac{R 8}{R 1}$
The scale factor $k$, dependent on the value of $R 8$, is chosen to meet the following criteria:

- compatibility with a standard capacitor from the E6 or E12 range for $Z_{\text {bal }}$
- $\left|Z_{\text {bal }} / / R 8\right| \ll$ R3 fulfilling condition (a) and thus ensuring correct anti-sidetone bridge operation
- $\left|Z_{\text {bal }}+R 8\right| \gg R 9$ to avoid influencing the transmit gain.

In practise $Z_{\text {line }}$ varies considerably with the line type and length. The value chosen for $Z_{\text {bal }}$ should therefore be for an average line length thus giving optimum setting for short or long lines.

## Example

The balance impedance $Z_{\text {bal }}$ at which the optimum suppression is present can be calculated by:

Suppose $Z_{\text {line }}=210 \Omega+(1265 \Omega / / 140 \mathrm{nF})$ representing a 5 km line of 0.5 mm diameter, copper, twisted-pair cable matched to $600 \Omega(176 \Omega / \mathrm{km} ; 38 \mathrm{nF} / \mathrm{km})$.

When $\mathrm{k}=0.64$ then $\mathrm{R} 8=390 \Omega$;
$Z_{\text {bal }}=130 \Omega+(820 \Omega / / 220 \mathrm{nF})$.
The anti-sidetone network for the TEA1060 family shown in Fig. 4 attenuates the signal received from the line by 32 dB before it enters the receiving amplifier.
The attenuation is almost constant over the whole audio-frequency range.
Figure 5 shows a conventional Wheatstone bridge anti-sidetone circuit that can be used as an alternative. Both bridge types can be used with either resistive or complex set impedances. (More information on the balancing of anti-sidetone bridges can be obtained in our publication "Applications Handbook for Wired telecom systems, IC03b", order number 939775000811.$)$

## LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

| SYMBOL | PARAMETER | CONDITIONS | MIN. | MAX. | UNIT |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {LN }}$ | positive continuous line voltage |  | - | 12 | V |
| $\mathrm{V}_{\text {LN(R) }}$ | repetitive line voltage during switch-on or line interruption |  | - | 13.2 | V |
| $\mathrm{V}_{\text {LN(RM) }}$ | repetitive peak line voltage for a 1 ms pulse per 5 s | $\begin{aligned} & \text { R9 }=20 \Omega ; \text { R10 }=13 \Omega ; \\ & \text { see Fig. } 18 \end{aligned}$ | - | 28 | V |
| $l_{\text {line }}$ | line current | R9 = $20 \Omega$; note 1 | - | 140 | mA |
| $\mathrm{V}_{1}$ | input voltage on all other pins | positive input voltage | - | $\mathrm{V}_{\mathrm{CC}}+0.7$ | V |
|  |  | negative input voltage | - | -0.7 | V |
| $\mathrm{P}_{\text {tot }}$ | total power dissipation <br> TEA1062; TEA1062A <br> TEA1062M1; TEA1062AM1 <br> TEA1062T; TEA1062AT | R9 = $20 \Omega$; note 2 |  | $\begin{aligned} & 666 \\ & 617 \\ & 454 \end{aligned}$ | mW <br> mW <br> mW |
| $\mathrm{T}_{\text {amb }}$ | operating ambient temperature |  | -25 | +75 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {stg }}$ | storage temperature |  | -40 | +125 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{j}}$ | junction temperature |  | - | 125 | ${ }^{\circ} \mathrm{C}$ |

## Notes

1. Mostly dependent on the maximum required $T_{\text {amb }}$ and on the voltage between LN and SLPE (see Figs 6, 7 and 8).
2. Calculated for the maximum ambient temperature specified ( $\mathrm{T}_{\mathrm{amb}}=75^{\circ} \mathrm{C}$ ) and a maximum junction temperature of $125^{\circ} \mathrm{C}$.

## HANDLING

This device meets class 2 ESD test requirements [Human Body Model (HBM)], in accordance with "MIL STD 883C - method 3015".

Low voltage transmission circuits with dialler interface

Voltage gain is defined as $\mathrm{G}_{\mathrm{v}}=20 \log \left|\mathrm{~V}_{\mathrm{o}} / \mathrm{V}_{\mathrm{i}}\right|$.
For measuring gain from MIC+ and MIC- the MUTE input should be LOW or open-circuit.
For measuring the DTMF input, the MUTE input should be HIGH.
Inputs not being tested should be open-circuit.

Fig. 14 Test circuit for defining TEA1062 voltage gain of MIC+, MIC- and DTMF inputs.

Low voltage transmission circuits with dialler interface

Voltage gain is defined as $G_{v}=20 \log \left|V_{o} / V_{i}\right|$.
For measuring gain from MIC+ and MIC- the $\overline{\text { MUTE }}$ input should be HIGH.
For measuring the DTMF input, the MUTE input should be LOW or open-circuit.
Inputs not being tested should be open-circuit.

# Low voltage transmission circuits with dialler interface 

## SOLDERING

## Plastic dual in-line packages

## BY DIP OR WAVE

The maximum permissible temperature of the solder is $260^{\circ} \mathrm{C}$; this temperature must not be in contact with the joint for more than 5 s . The total contact time of successive solder waves must not exceed 5 s .

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

## Repairing soldered joints

Apply the soldering iron below the seating plane (or not more than 2 mm above it). If its temperature is below $300^{\circ} \mathrm{C}$, it must not be in contact for more than 10 s ; if between 300 and $400^{\circ} \mathrm{C}$, for not more than 5 s .

## Plastic small-outline packages

By wave
During placement and before soldering, the component must be fixed with a droplet of adhesive. After curing the adhesive, the component can be soldered. The adhesive can be applied by screen printing, pin transfer or syringe dispensing.

Maximum permissible solder temperature is $260^{\circ} \mathrm{C}$, and maximum duration of package immersion in solder bath is 10 s , if allowed to cool to less than $150^{\circ} \mathrm{C}$ within 6 s . Typical dwell time is 4 s at $250^{\circ} \mathrm{C}$.

A modified wave soldering technique is recommended using two solder waves (dual-wave), in which a turbulent wave with high upward pressure is followed by a smooth laminar wave. Using a mildly-activated flux eliminates the need for removal of corrosive residues in most applications.

## By SOLDER PASTE REFLOW

Reflow soldering requires the solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the substrate by screen printing, stencilling or pressure-syringe dispensing before device placement.
Several techniques exist for reflowing; for example, thermal conduction by heated belt, infrared, and vapour-phase reflow. Dwell times vary between 50 and 300 s according to method. Typical reflow temperatures range from 215 to $250^{\circ} \mathrm{C}$.
Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 min at $45^{\circ} \mathrm{C}$.

Repairing soldered Joints (by hand-held soldering IRON OR PULSE-HEATED SOLDER TOOL)

Fix the component by first soldering two, diagonally opposite, end pins. Apply the heating tool to the flat part of the pin only. Contact time must be limited to 10 s at up to $300^{\circ} \mathrm{C}$. When using proper tools, all other pins can be soldered in one operation within 2 to 5 s at between 270 and $320^{\circ} \mathrm{C}$. (Pulse-heated soldering is not recommended for SO packages.)

For pulse-heated solder tool (resistance) soldering of VSO packages, solder is applied to the substrate by dipping or by an extra thick tin/lead plating before package placement.

## DEFINITIONS

| Data sheet status |  |
| :--- | :--- |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values |  |
| Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or <br> more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation <br> of the device at these or at any other conditions above those given in the Characteristics sections of the specification <br> is not implied. Exposure to limiting values for extended periods may affect device reliability. |  |
| Application information |  |
| Where application information is given, it is advisory and does not form part of the specification. |  |

## LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
